3650. STRUTCHOFF M.I. * The phenomenon of 'switching' in heterogeneous conditioned reflexes (Russian text) Z. VYSC. NERV. DEJATEL. 1955, 5/4 (547-554) Graphs 7

Experiments were performed on 2 dogs in 2 experimental chambers. In the 1st chamber an alimentary conditioned reflex to acoustic and visual stimuli and a defensive conditioned reflex to a tactile stimulus were elaborated. Then, in the 2nd chamber, the same acoustic and visual stimuli were used as defensive stimuli while the tactile stimulus was used as an alimentary stimulus. Experiments in the 1st chamber were continued alternately with those in the 2nd chamber. At first, in both experimental chambers defensive and alimentary reflexes to all the conditioned stimuli were intermingled, but gradually the dogs learnt to respond to a given stimulus with the proper reaction, depending on the chamber in which the experiment was conducted.

~~PLANT GROWTH, MITOSIS~~

ABSTRACT: Tests on the exposure of separate sections of Vicia faba, with the remaining part of the plant carefully screened, indicate the formation of a number of metabolites under the influence of such exposure. The metabolites, called radio-inductors (RI), migrate to the unexposed parts and inhibit cell division in them. The inhibiting of mitosis is observed even after wetting the growths in extracts from exposed plants. The quantity of radio-inductors formed during a determined range of doses increases with the dosage. The authors suggest that the products of oxidation of phenol derivatives, in particular those of the oxidizing disintegration of tyrosine, may be the inhibitors of cell division. Theoretically, the products of the fermentative oxidation of tyrosine include dehydrophenylalanine, various quinones, and high-polymer melanines, some of which possess properties of free radicals and powerful oxidizers. The formation of the carbohydrates mentioned provides experimental

Card 1/2

1 UDC: 577.3

ACC NR: AR6000469

corroboration for the study of products from the exposed leaves by the method of chromatography and EPR. Model tests on inhibiting mitosis after the addition of tyrosine, tyrosinase, and melanines indicate that these carbohydrates are radio-inductors. The authors suggest that the intermediate products of the oxidation of tyrosine found in a free radical state can form complexes with DNA and exclude it from the cycle of changes necessary for the beginning of mitosis. ✓4000. Biochemical transformations of purine precursors. G. A. Kritskii and V. A. Struchkov *Biokhimiia*, 1956, 21, 196-202 (Inst. Biochem., Acad. Sci., Moscow, U.S.S.R.).—Typical products of biochemical reactions of purine precursors ([^{14}C]glycine, [$^{14}\text{CO}_2$, and [^{14}C]formic acid) were demonstrated by paper chromatography and radiation analysis. 12 fractions were obtained (hypoxanthine, adenosine, inosine, etc.). It was found that glycine and methionine had the most profound effect on these reactions (mainly stimulating). Aspartic acid, pyruvate and rutose 5-phosphate were less effective. Also investigated were some properties of unidentified radioactive products of biochemical reactions of [^{14}C]glycine, [$^{14}\text{CO}_2$ and [^{14}C]formic acid. (Russian) A. K. Grzybowski

TITLE:

A study of change in the state of deoxyribonucleic
acid in Escherichia coli exposed to gamma-radiation

PERIODICAL:

Radiobiologiya, v. 1, no. 4, 1961, 476-478

TEXT: It was found that irradiation of hens in a dose of 2.5 kr led to an immediate change of 50% in the structuro-mechanical properties of the secreted polymolecular deoxyribonucleic acid (DRN) complexes. This points to disturbance of the crude state of DRN in the cell. To check whether this phenomenon has a general significance in radiation biology, the authors studied the state of DRN in E. coli before and after irradiation. The DRN state and the effects of radiation at various stages in the bacterial strain's development were also studied. Tests were run on a young 16-hour and a stationary 46-hour culture of

Card 1/3

A study of changes...

E. coli var. B, irradiated by gamma-rays from a Co^{60} source in a dose of 4 kr (LD_{31} for the particular strain) at an intensity of 450 r/min. and at 37°C and 20°C . The structuro-mechanical properties of the DRN were measured with a capillary elastoviscosimeter at 25°C and the results expressed as values of the relative viscosity η_{rel} . The results showed that DRN in the young E. coli culture was in a special state, characterized by the high structuro-mechanical properties of its solutions ($\eta_{\text{rel}} = 200 \text{ dl/g}$). The stationary E. coli culture contained DRN in a qualitatively different state, with a η_{rel} value of 100 dl/g.

Immediately after irradiation, changes of 50% in the structuro-mechanical properties of the DRN were noted in the young E. coli culture, whereas in the old culture these properties showed no practical change. The authors deduce from this that there is a special state of DRN characteristic of young mitotic cells, and that this is linked directly with their sensitivity to radioactivity. There are 2 tables and 4 references:

Molecular Structure of DNA and Radiation Damage to Cells

N. B. Strazhevskaya and V. A. Strelkov

In previous investigations the authors demonstrated in various cell types (erythrocytes and bone marrow of chickens, *E. coli*, fibroblast aves cells) the high radiation-sensitivity of the macromolecular DNA structures. In this investigation the authors studied the dynamics of the state of macromolecular DNA structures as a function of dose (50, 250, 500, 1000 and 5000 r) and of the time after γ -irradiation of rats (0.25, 1, 2, 4, 6, 8, 21 and 45 hr) in organs with different radiation sensitivity (thyroid and liver). It was found that a distinct disturbance in the physico-chemical state of the macromolecular DNA structure in the thyroid and liver is observed immediately after irradiation of rats. The magnitude of the effect depends on dose. In the thyroid this relationship is of an exponential nature for doses below 1000 r. The further fate of the macromolecular structure of DNA after irradiation is different for the radiosensitive and radioresistant tissues. In the thyroid the changes of the macromolecular structure of DNA are irreversible, whereas in the liver this process is reversible. However, in the regenerating liver the disturbance of these structures following irradiation becomes irreversible, as in the case of thyroid.

It is suggested that the radiosensitivity of the cell is determined by the special state of the macromolecular DNA structure (thyroid) and by the presence of some mechanisms which are able to restore these structures (liver).

Institute of Biological Physics of the Academy of Sciences of the USSR, Moscow

The Initial Stages of Radiation Injury to DNA Structure

V. I. Tokarskaya

Our results confirm the assumption of a point injury in the structure of DNA molecules during irradiation, the point of injury being thymine. Observations on dry seeds and on isolated DNA showed that the injuries to the structures are of a potential nature and develop in the presence of water. The effects of neutron or γ -irradiation on the DNA structure of seeds were different.

Using ^{35}S labelling it was shown that the changes in the template result in faulty synthesis and the DNA synthesized after irradiation has a qualitatively different composition.

To explain the remote effects of radiation on DNA it is suggested that loops are formed in the structure of irradiated DNA due to the loss of thymine.

816. CHANGES IN CARDIOVASCULAR ACTIVITY DURING AND AFTER
RADICAL OPERATIONS UPON THE LUNGS (Russian text) - Struchkov
V. I., Skripnichenko D. F., Fedorov B. K. and Parfenov
A. P. - VESTN. KHIR. 1956, 7 (64-70)

This work surveys the results of study of cardiovascular activity during and after radical lung operations on 170 patients. Particularly marked and prolonged changes in cardiac action were observed after removal of a lung or ligation of its vessels. Alterations of blood pressure were observed in the course of the first 48 hr.; oscillographic and oscillometric investigations were testified to changes in vascular tonus after lung operations. Normalization of the vascular tonus at rest took place on the 10th-14th day after operation. After lobectomies and segment resections the rate of the blood circulation did not change substantially; after removal of a lung and ligation of the pulmonary artery the rate of the blood circulation increased to 1.5 times the pre-operative rate. The cardiovascular action does not become fully compensated until 5-6 months after the operation. (S)

2420. COLLATERAL CIRCULATION IN INJURY OF THE BLOOD VESSELS
(Russian text) - Struchkov V. I. - KHIRURGIJA 1957, 5 (73-77) Tables 1
On the basis of observations of 3298 patients with gun-shot wounds and injuries of the large blood vessels the author discusses the value of anatomical as well as functional collaterals of different major blood vessels. The development of collateral circulation in them is different. This should be taken into consideration in choosing a method of surgical intervention. Special attention is paid to consideration of the functional condition of collaterals immediately after the injury. Measures to increase their width are to be taken at once in order to prevent gangrene of the extremity. Prevention and treatment of shock, acute anaemia, increasing

2420

haematomas, chilling, fatigue, wound infection, assist the maximum development of collaterals. Great significance is also attached to gentle operating technique and good anaesthesia. The analysis of all factors that hinder development of collateral circulation and the measures which aid in recovery of circulation are fully discussed in this paper.

STRUCHKOV V.I.
2762. THE PLEURAL CAVITY AFTER RADICAL LUNG OPERATIONS (Russian
text) - Struchkov V.I. and Skripnichenko D.F. - KHIRURGIYA
1957, 7 (26-30)

The experience with 273 cases is reviewed. Pulmonectomy had been performed in 94 patients, bilobectomy, lobectomy and segmental resection in 144, while 35 were subjected to ligation of pulmonary artery, thoracotomy, etc. The different methods of treatment of pleural cavity were studied i.e. prolonged drainage, drainage during 48 hr. and complete closure of pleural cavity with drainage by means of puncture following. The latter was carried out in lobectomy, beginning directly after the operation and in pulmonectomy on various indications. The most important indication for drainage is the presence of symptoms of displacement of mediastinal organs by accumulating exudate. Antibiotics were regularly introduced into the pleural cavity in all cases. Lately, before the suture of thoracic wall, the parietal pleura was infiltrated by antibiotics dissolved in novocaine solution. It is pointed out that after bilobectomies, lobectomies and segmental resections the pleural cavity is filled by the dilated residual portion of the lung, by elevation of the diaphragm and partly by development of fibrothorax. After pulmonectomies the cavity is filled by raised diaphragm, displaced mediastinal organs, collapsed thoracic wall and fibrothorax. The latter is formed from pleural exudate. Treatment of pleural cavity by the closed method, without drainage, is recommended.

1076. DIFFERENTIAL DIAGNOSIS OF PERIPHERAL DISINTEGRATING PUL-
MONARY CANCER AND LUNG ABSCESS (Russian text) - Struchkov
V. I., Vol-Epshtein G. L. and Grigoryan A. V. - VESTN.

KHIR. 1957, 79/9 (45-48 and 157) Tables 1 Illus. 4

Twenty-five cases of patients with disintegrating peripheral lung cancer and 25 instances of pulmonary abscesses were studied. Tomography as an adjuvant method of roentgenological investigations has an outstanding diagnostic value in these cases. It visualizes the shape of the structure, its cavities and their details, the outline of the inner wall and of lung sequestra. A clear-cut polycyclic bulging shape of the round shadow with a cavity inside is found to exclude a lung abscess and to mean that a disintegrating cancer in the period of extensive growth is present. Sometimes a disintegrating peripheral pulmonary cancer in the stage of infiltrative growth may be tomographically differentiated from an abscess.

Struchkov V. I., Skrupnichenko D. F. and Sakharov K. A. -
NOV. KHIR. ARKH. 1958, 1 (32-38) Tables 1

A follow-up from 1-4 yr. after surgical treatment. 120 cases are analysed. The best long-term results were obtained by lobectomy and segmental resection. Pneumonectomy was followed by some cardiopulmonary disturbances, such as functional hypertrophy of the right heart, diminution of gas exchange, increase of difference in O₂ contents in venous and arterial blood and also decrease of the coefficient of O₂ utilization by the tissues. These cardiopulmonary disturbances were partly compensated during the first 8-12 months after surgery.
